

1) Dependency Parsing

Constituency Parsing :

2) Content Free Grammar: Rule Set:

$S \rightarrow NP \ VP$

$NP \rightarrow \text{det}(\?) \ NP \mid N$

$VP \rightarrow VP \ PP^+ \ S'(\?) \mid VP \ NP \mid TO \ VP \mid VG \ VP \mid V$

$PP \rightarrow P \ NP \mid P \ S'$

$S' \rightarrow VP$

$VG \rightarrow V$

Part-of-speech \rightarrow height 1 nodes:

N : noun

V : verb (not differentiating between verb forms.)

det : determinant

P : preposition

TO : "to"

NOTE : Using universal dependency notation for the depending parsing & a modified version of standard constituency parse labels. Refer to the CFG for better understanding.
A similar notation was followed in courses like 'Introduction to Linguistics', & 'Computational Linguistics - I'.

3) Sentence 1: Word Form: drop

Feature Structure: $\left[\begin{array}{cc} \text{root} & \text{drop} \\ \text{agr} & \left[\begin{array}{cc} \text{tense} & \text{Present} \\ \text{aspect} & \text{Simple} \\ \text{voice} & \text{Passive} \end{array} \right] \end{array} \right]$

Sentence 2 : Word Form: dropping

Feature Structure: $\left[\begin{array}{cc} \text{root} & \text{drop} \\ \text{agr} & \left[\begin{array}{cc} \text{tense} & \text{Present} \\ \text{aspect} & \text{Progressive} \\ \text{voice} & \text{Passive} \end{array} \right] \end{array} \right]$

Sentence 3 : Word Form: dropped

Feature Structure: $\left[\begin{array}{cc} \text{root} & \text{drop} \\ \text{agr} & \left[\begin{array}{cc} \text{tense} & \text{Past} \\ \text{aspect} & \text{Simple} \\ \text{voice} & \text{Passive} \end{array} \right] \end{array} \right]$

& Clause: having dropped:

Feature Structure: $\left[\begin{array}{cc} \text{root} & \text{drop} \\ \text{agr} & \left[\begin{array}{cc} \text{tense} & \text{Present Perfect} \\ \text{aspect} & \text{Simple} \\ \text{voice} & \text{Passive} \end{array} \right] \end{array} \right]$

- The roots for all the verbs is the same. We can differentiate between the verb forms using 'tense' & 'aspect' features.

- Having feature specifications reduces the number of CFG rules. Let's say our CFG would capture all the granularity as seen by the feature specification.

This leads to having 3 different tags/labels for height 1 nodes in the CFG trees (leading to leaves) for the 3 different verbs. e.g: VB for 'drop', VBG for 'dropping', VBD for 'dropped', etc.

But in feature specification; verbs can be captured by only 1 rule. The feature matrix handles the syntactic granularity. As one moves bottom-up from leaf nodes, overtly specific features & predicates may be pruned out, further reducing the complexity. e.g: We may choose to prune out IT-phrases & ADVCLs. Clearly, the number of rules will be less while using feature specifications.

4) For the 3 sentences:

Word Form: mother, clause: 'The mother'

feature specification: $\left[\begin{array}{cc} \text{spec} & \text{definite} \\ \text{root} & \text{mother} \\ \text{agr} & \left[\begin{array}{cc} \text{number} & \text{singular} \\ \text{gender} & \text{female} \end{array} \right] \end{array} \right]$

Word Form : goes

Feature Specification:
$$\left[\begin{array}{cc} \text{root} & \text{go} \\ \text{agr} & \left[\begin{array}{cc} \text{tense} & \text{Present} \\ \text{aspect} & \text{Simple} \end{array} \right] \\ \text{number} & \text{singular} \end{array} \right]$$

Now, while finding the specification of higher forms →
'The mother goes' : 'number' is seen as a common feature. Hence, an agreement check is conducted.
Since: values of both specifications have 'singular' for number, the unification is accepted.
